# Introto Agural Networks

**BA865 – Mohannad Elhamod** 

## Language Modeling

Web search engine / ...

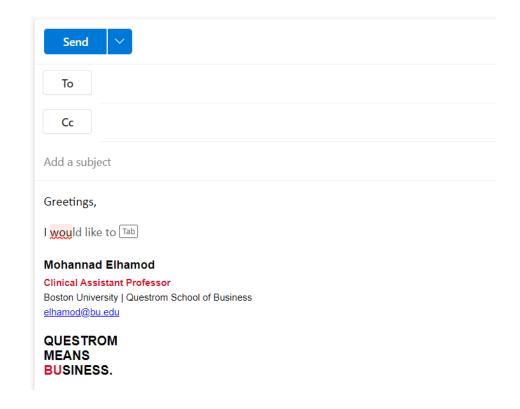

I saw a cat |

I saw a cat on the chair

I saw a cat running after a dog

I saw a cat in my dream

I saw a cat book

Lena-voita

I grabbed the branch and broke it.

I went to the branch and deposited some money.

**Context matters!** 

- I went to \_\_\_\_\_.
- I woke up at 7 am and went to \_\_\_\_.
- I woke up at 7 am, packed my book and notebook, and went to \_\_\_\_\_.

#### More context leads to more certainty

I went to the branch and deposited some money.

I went to the bank and deposited some money.

I went to the ATM and deposited some money.

Words which frequently appear in similar contexts have similar meaning.

Lena-voita

#### Formalizing our thoughts

- It seems we process language sequentially\*\*.
- So, language modeling is the chaining of word probabilities.

```
P(\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat} \quad \text{on} \quad \dots) = \\ P(\mathbf{I}) \cdot P(\mathbf{saw}|\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{cat}|\mathbf{I} \quad \text{saw} \quad \mathbf{a}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ Probability of \mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat} \quad \text{on} \\ \\ P(\mathbf{I}) \cdot P(\mathbf{saw}|\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{cat}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{cat}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{a}|\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{on}|\mathbf{I} \quad \text{saw} \quad \mathbf{a} \quad \text{cat}) \quad \dots \\ P(\mathbf{I}) \cdot P(\mathbf{I} \quad \text{saw}) \cdot P(\mathbf{
```

How do we calculate these probabilities?

$$P(\text{cat}) = \frac{N(\text{"cat" in corpus})}{N(\text{all words in corpus})}$$

$$P(\text{cat } | \text{ my}) = \frac{N(\text{"my cat" in corpus})}{N(\text{"my" in corpus})}$$

Lena-voita

Can you foresee any problem with this calculation?...

#### N-grams

Instead, let's just use a context of fixed-length.

P(I saw a cat on a mat) =

P(I)

- · P(saw | I)
- · P(a | I saw)
- · P(cat | I saw a)
- · P(on | I saw a cat)
- · P(a | I saw a cat on)
- · P(mat | I saw a cat on a)

Lena-voita

- ullet n=3 (trigram model):  $P(y_t|y_1,\ldots,y_{t-1})=P(y_t|y_{t-2},y_{t-1}),$
- n=2 (bigram model):  $P(y_t|y_1,\ldots,y_{t-1})=P(y_t|y_{t-1}),$
- n=1 (unigram model):  $P(y_t|y_1,\ldots,y_{t-1})=P(y_t).$

#### N-grams

Context is like a sliding window into the past.

Hugging Face is a startup based in New York City and Paris p(word)

Huggingface

#### **Context size**

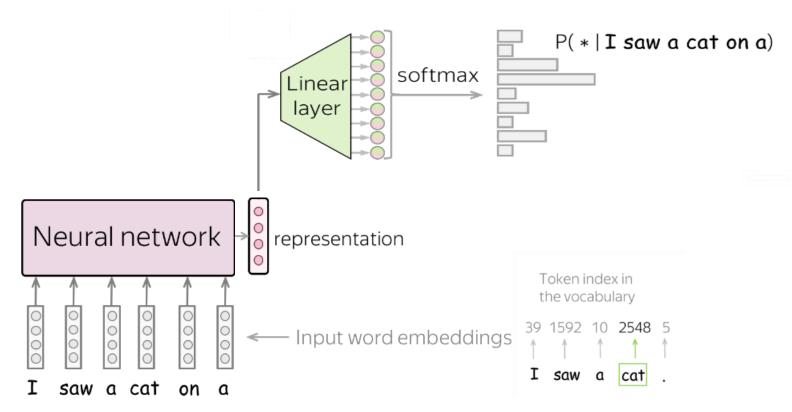

- I went to the beach...
- My wife sat next to me. She was replying to some emails, and...
- the bird stole our sandwich. Then...
- it started raining suddenly and \_\_\_\_\_.
- Longer context: predictable outcome.
- Shorter context: Too unpredictable.

## AAITA Networks Language Modelina

#### **General Model Architecture**

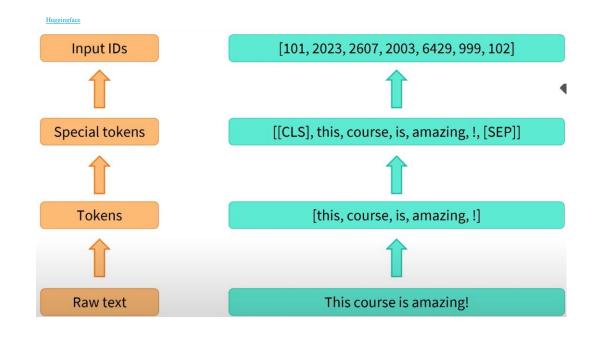

Can you see any issue with inputting words into an NN?

#### **Tokenization**

- Computers only understand numbers.
- We need to convert the text into tokens (e.g., words).
- Can we use the Input IDs as representation?
- Is it a good representation?

Mohannad Elhamod – BA820 4/11/2024

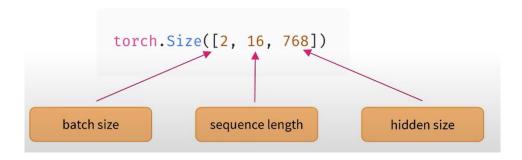

#### Syntax vs. Semantics

- Notice that:
  - Different tokens might have the same meaning (e.g., like, enjoy)
  - The same token might have different meanings (is like something, to like something)
- So, while tokens represent syntax, we really care about meaning/semantics.
- In many cases, you can only get the meaning through <u>context</u> (i.e., the token's place with respect to other tokens.)

#### **Vectorization**

- Once tokenized, we convert the tokens into vectors.
- So, if we have a dataset of sentences, we represent them as:
  - A <u>batch</u> of sentences (i.e., batches)
  - Each sentence is represented as a sequence of tokens (sequence length)
  - Each token is represented as a vector (hidden size)

#### **Word Embeddings**

- We ideally want words that have similar meanings to have smaller distances.
- Demo
- Examples:
  - 1. Word2Vec (Google)
  - 2. GloVe (Stanford)
  - 3. Train your own!

#### Word embeddings

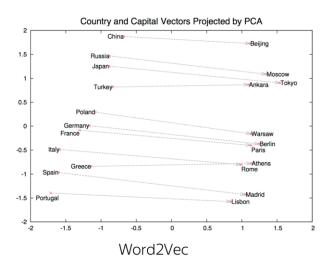

Word embeddings can also be used find directionality in the corpus:

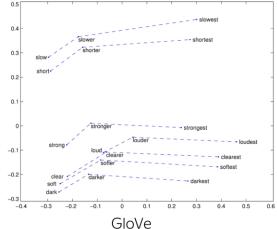

- Demo 1 (semantics)
- Demo 2 (vector view)
- Demo 3 (dimensionality)

#### Word embeddings

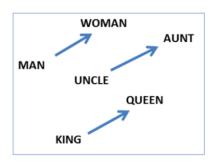

Word embeddings can also be used find directionality in the corpus.

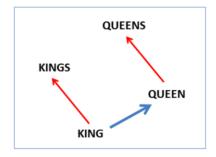

syntactic: 
$$v(kings) - v(king) + v(queen) \approx v(queens)$$

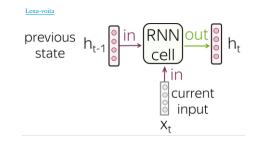

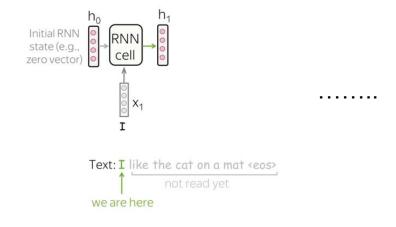

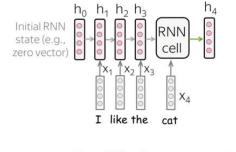

#### **Recurrent Neural Nets (RNNs)**

- Wouldn't it be nice if the model kept a "memory" of the previous state?
- The model could combine the embedding of the "memory" and current word → gives next word.

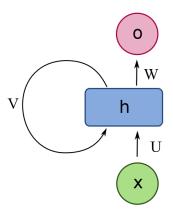

Mohannad Elhamod – BA865 4/11/2024

#### What is an "RNN cell"?

#### It is just a set of matrices:

- U <u>encodes</u> current input into an embedding.
- V <u>transforms</u> the embedding representing the context up to this point.

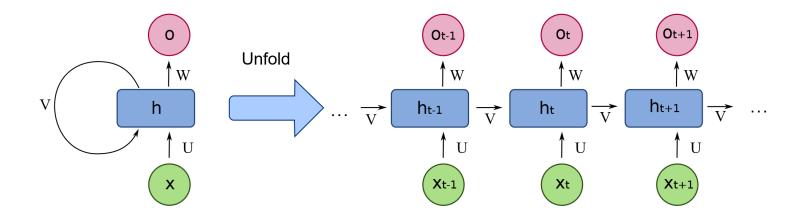

Mohannad Elhamod – BA865 4/11/2024

#### What is an "RNN cell"?

#### It is just a set of matrices:

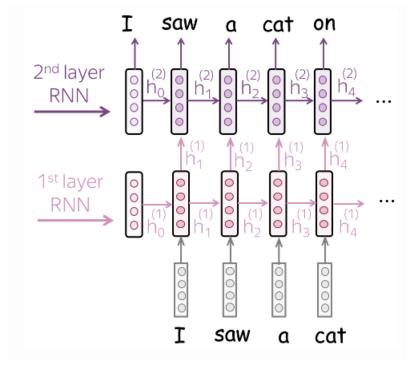

- h is a new embedding representing <u>a combination</u> of the context embedding and the current word embedding.
- W <u>decodes</u> the new embedding back into a prediction.

#### **Recurrent Neural Nets (RNNs)**

- We can add more layers and units per layer to increase complexity.
- Demo

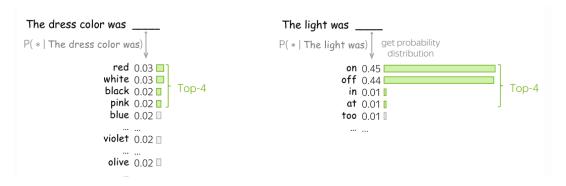

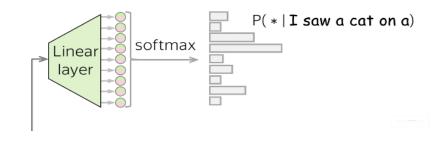

Lena-voita

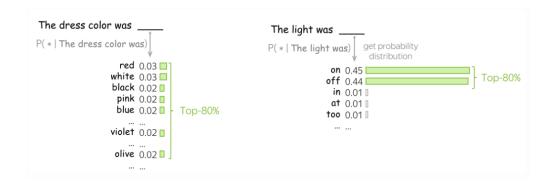

#### **Sampling The Distribution**

- Always take top probability?
  - That makes the model deterministic (no creativity).
- Alternative?
  - Sampling, Top-k, or top-p.

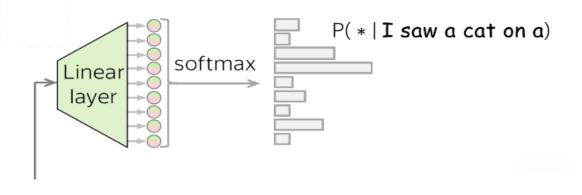

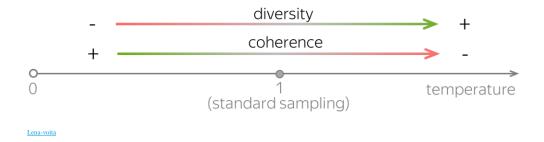

#### **Sampling The Distribution**

- Some words have way higher probability than others.
- This can be manually tuned through temperature.
- Demo

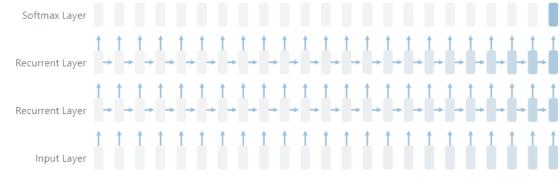

#### **Measuring The Metric**

- What are we looking for?
  - A model that is <u>not surprised</u> by the <u>new</u> text it seen.
- We use perplexity.
  - Takes values between 1 and number of possible tokens.
  - Smaller is better.
  - Demo

#### RNNs (issues)

- Gradient becomes insignificant for long contexts
  - The network forgets early words...
  - It is called the "vanishing gradient" or "memorization" problem.
  - RNNs have an issue memorizing long contexts.

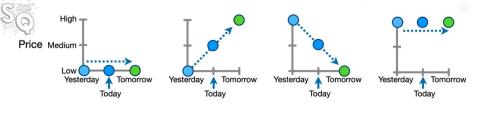

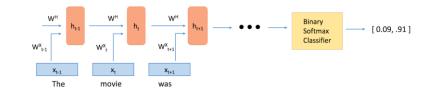

Vanishing Gradient: where the contribution from the earlier steps becomes insignificant in the gradient for the vanilla RNN unit.
